Lecture 7 - Control Flow / If Statements

- 1. We are working on the grading.
- 2. Assignment 2 too hard.

Using GIT and Github.com

We are basically following most of the steps in https://product.hubspot.com/blog/git-and-github-tutorial-for-beginners.

https://www.freecodecamp.org/news/how-to-undo-a-git-add/

1st Test Question

```
1:
 2: def feet_to_inches ( feet ):
        conv = 12
 4:
        inches = feet * conv
 5:
        return ( feet )
 6:
 7: # Automated Test
 8: if __name__ == "__main__":
 9:
        n err = 0
10:
        x = feet_to_inches (1)
        if x != 12:
11:
12:
            n_{err} = n_{err} + 1
13:
            print ( "Error: Test 1: conversion not working, expected {} got {}".format
14:
        x = feet to inches (0)
15:
        if x != 0:
            n_{err} = n_{err} + 1
16:
17:
            print ( "Error: Test 2: conversion not working, expected {} got {}".format
18:
19:
        if n err == 0:
            print ( "PASS" )
20:
21:
        else:
22:
            print ( "FAILED" )
23:
```

1. (10pts) The above code has something wrong with it. When the test is run it says "FAILED". Correct the code.

Where we are so far...

- 1. Installs usually hard and unpleasant.
- 2. Using some files where paths directories/folders.
- 3. Fixing some code changes break thins then you have to fix it.
- 4. Testing. Thomas Piketty, "Capital in the Twenty-First Century". https://www.reuters.com/article/idUS268051827620140527 "The Financial Times has launched a critique of the data behind the French economist's bestseller "Capital in the Twenty-First Century." ... he has also fallen prey to sloppy spreadsheets."
- 5. Functions

```
def fucntion_name ( input1, input2 ):
# do_someting... with input1, input2
# produce some output
return ( output )
```

6. Input a number - differences between strings and numbers and integers and floats

"if" / True / False

Operators that commonly go into expressions in if:

```
compare for equality
!= not equal
less than
preater than
less than or equal
preater than or equal
```

An Example:

The ski area sells tickets and gives a discount based on age. Adult tickets age 18-69 are \$59, Youth 5-12 are \$40, Teen are \$52, Children 4 and under are free, seniors 70 and older are free.

```
1:
 2: print ( "Input Age\n=> ", end="" )
 3: age_str = input()
4: age = int(age_str)
5:
6: ticket_price = 0
7: if age <= 4:
       ticket_price = 0
8:
9: elif age >= 5 and age <= 12:
10:
       ticket_price = 40
11: elif age >= 13 and age <= 17:
12:
       ticket_price = 52
13: elif age >= 18 and age <= 70:
       ticket_price = 59
15: else:
16:
        ticket_price = 0
17:
18: print ( "Ticket Price ${}.00 dollars".format(ticket_price) )
```

Order of Evaluation

```
1:
 2: print ( "Input Age\n=> ", end="" )
 3: age str = input()
 4: age = int(age_str)
 5:
 6: ticket_price = 0
 7: if age <= 4:
 8:
        ticket price = 0
 9: elif age <= 12:
       ticket price = 40
11: elif age <= 17:
12:
       ticket_price = 52
13: elif age <= 70:
        ticket_price = 59
14:
15: else:
16:
        ticket_price = 0
17:
18: print ( "Ticket Price ${}.00 dollars".format(ticket_price) )
```

Common Errors - leaving out cases in the logic.

```
1:
2:
3: print ( "Input Age\n=> ", end="" )
4: age_str = input()
5: age = int(age_str)
6:
7: ticket_price = 59
8: if age <= 4:
9:     ticket_price = 0
10: elif age <= 12:
11:     ticket_price = 40
12: elif age <= 17:
13:     ticket_price = 52
14:
15: print ( "Ticket Price ${}.00 dollars".format(ticket_price) )</pre>
```

"and" and "or"

When we have "if" the expression is true or false as values.

There are operators that work on Boolean values. These are *or*, *and*, *not* and an exclusive or operator, ^.

```
a = 2

b = 3

r = (a == 2) and (b == 3)
```

Truth Tables

And:

Α	В	A and B
False	False	False
False	True	False
True	False	False
True	True	True

Or:

Α	В	A or B
False	False	False
False	True	True
True	False	True
True	True	True

Exclusive Or:

Α	В	A ^ B
False	False	False
False	True	True
True	False	True
True	True	False

Not:

Α	not A
True	False
False	True

calling functions

You can also make a function (def) that returns a True/False value and use that in an if.
